

AperCal – The Apertif Calibration Pipeline

A large radio telescope dish is the central focus in the foreground, its complex metal lattice structure clearly visible. It is mounted on a tall, dark support structure. In the background, several other similar dishes are visible, receding into the distance. The sky is a vibrant blue, filled with soft, white cumulus clouds. The ground is a flat, grassy field, and a line of dark evergreen trees is visible in the far background. The overall scene is captured in a slightly low-angle perspective, emphasizing the scale of the telescope.

Björn Adebahr
Ruhr-Universität Bochum

AperCal structure

- CASA and MIRIAD routines using a jupyter notebook framework
- Calibration/Imaging steps are independent software routines (modules)
- All 40 beams are processed independently and in parallel

AperCal output data products

APERTIF output products are arranged in levels depending on the needed effort to create them

Level 0

- Raw uncalibrated visibilities

Data from the telescope

Level 1

- Calibrated visibilities for each beam

Level 2

- Continuum images of individual beams and mosaics
- Line cubes with full frequency resolution
- Stokes Q and U cubes with ~ 0.8 MHz resolution
- Stokes V images
- Spectral index maps

Pipeline reduction

Level 3

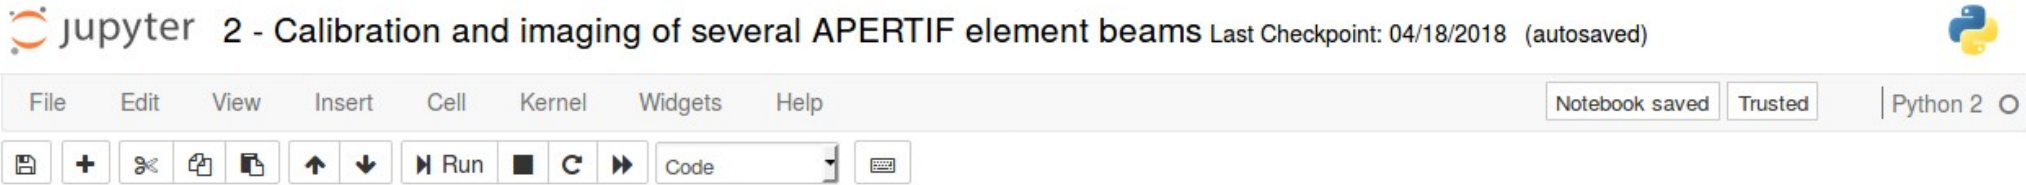

- Sub-cubes for line sources
- Moment 0 and 1 maps
- RM-cubes
- Electric field vector images (PA)
- Magnetic field vector images (PA0)
- Polarised intensity images (linear and circular)

Reduction within
the pipeline framework

AperCal automatic processing

- Config file for each observation and beam with standard parameters
- Future development: Find optimal parameters depending on type of observed field

First we reduce all beams with the same standard parameters.

```
In [2]: scal = apercal.scal('/home/{}/apercal/ipython-notebooks/tutorials/cfg/2.cfg'.format(myusername))
scal.show()

AperCal user interaction

- Parameters can be temporarily changed by the user in the interface
- We will never reach a 100% success rate for the calibration

The screenshot shows a Jupyter Notebook window titled "2 - Calibration and imaging of several APERTIF element beams". The interface includes a menu bar (File, Edit, View, Insert, Cell, Kernel, Widgets, Help), a "Trusted" status indicator, and a "Python 2" kernel selection. The notebook contains three code cells:

```
In [ ]: import subs  
  
scal.beam = '01'  
scal.reset()  
  
Then change the parameter you want to change temporarily, for example scal.parametric = False .  
  
In [ ]: scal.parametric = False  
  
And then start the selfcal for this beam.  
  
In [ ]: scal.go()
```

Keep the complex information the pipeline produces

BUT

Summarise the information for the user so that (s)he can find the problem

AperCal summaries

- Summaries intend to provide the user with the necessary information to find problems
- Reads the complex information from the pipeline reduction and shows at which step the calibration/imaging failed

```
In [4]: ds = mosaic.detailed_summary_continuumstacked()
ds.style

d = dict(selector="th", props=[('text-align', 'center')])
ds.style.set_properties(**{'text-align': 'center'})
```

Out[4]:

	Continuum calibration?	Copy successful?	Bmaj ["]	Bmin ["]	Bpa [deg]	Beam parameters?	Convol successful?	Weight	Residual RMS	Image accepted?
00	True	True	18.28	14.02	-0.83	False	False	nan	nan	False

16	False	False	nan	nan	nan	False	False	nan	nan	False
17	False	False	nan	nan	nan	False	False	nan	nan	False

Metrics

- Have to validate a calibration step or data product
- Stabilise the pipeline runs
- Only two values possible (a computer only understands True or False)
- Exact values often specific to a certain system/telescope

Some examples for selfcal/continuum imaging (implemented in AperCal):

- Is the rms of the final residual images unrealistically high?
- Are the statistics of the final residual images Gaussian?
- Is the cleaning mask occupying a large percentage of the image?
- Do the clean components show unrealistic high or low values?
- Does the summarised flux of the clean components after amplitude calibration significantly differ from the previous phase only calibration?
- If one of the above is flagged as bad use the solutions/images from the previous cycle

AperCal multi-frequency continuum image of S2246+38

- All 40 beams calibrated successfully
- 300 MHz bandwidth (220 MHz effectively)
- Created without human interaction within 24 hours of processing time
- Noise $\sim 40 \mu\text{Jy}/\text{beam}$

Improvements possible with

1. Amplitude calibration
2. Only use RFI free areas for calibration and imaging

First Apertif polarised intensity image

- 20% of the band used for this image (Q-/U-imaging + RM-Synthesis)
- Leakage looks good, but needs to be quantified
- Polarisation angle needs to be checked
- Optimisation of calibration strategy (stability of leakage and polarisation angle solutions)

Future AperCal improvements

Tests by Alexander Kutkin using KillMS

- On average takes the same time as the MIRIAD selfcal and continuum modules
- Same parameters can be used for nearly all fields (11 facets)
- Not as stable as standard selfcal and continuum imaging (2/40 beams failed)

Future AperCal improvements

Short term (until surveys start in July)

- Option to split out a part of the band for a Quicklook pipeline and reduce data size
- Optimising pybdsf masking parameters
- Implement primary beam shape into parametric selfcal and mosaicking module

Long term (after surveys start)

- Dynamic range improvements (Peeling/DD-calibration, different parameters)
- Fully cleaned line cubes
- Data analysis framework
 - Continuum, polarisation and HI source finding
 - Automatic catalogue creation
 - Faraday cube reduction (PI-, PA-, RM-maps)
